

# Proposed Associations with PPI Use

	Summary Evidence
<b>Renal Function Decline</b>  1. Lazarus et al. JAMA Int Med Feb 2016 2. Antoniou et al. CMAJ Open April 2015	<ul style="list-style-type: none"> <li>NIH-funded cohort trial evaluating risk of new onset CKD in patients receiving PPIs relative to H2 blockers and no antisecretory therapy. Included &gt;27,000 adults ages 45 - 64 and a baseline GFR &gt;60 mg from two US databases.<sup>1</sup></li> <li>After adjusting for multiple factors including age, DM, HTN, diuretic and NSAID use, patients receiving PPIs were 20 - 50% more likely to develop CKD relative to patients receiving no antisecretory therapy.</li> <li>The 10-year absolute risk difference of developing CKD on a PPI was estimated as 1.7% - 3.3%. (NNH: 30 - 58 patients treated for 10 years).</li> <li>No significant increase in CKD was noted among patients receiving H2 blockers.</li> <li>Consistent with previous literature, this trial showed an increased risk of AKI with PPI use.<sup>2</sup></li> </ul>
<b>Dementia</b>  3. Gomm et al. JAMA Neurology April 2016 4. Haenisch et al. Eur Arch Psych Clin Neurosci Aug 2015	<ul style="list-style-type: none"> <li>Review of German claims database. Included patients age ≥75 years with no prior diagnostic claims for dementia and regular prescription claims for a PPI during an 18 month period.<sup>3</sup></li> <li>After adjusting for age, gender, stroke, depression, and polypharmacy, frequent claims for a PPI was associated with a 44% increase risk of claims for dementia. While the use of claims data adds level of uncertainty, the results were consistent with the authors' previous findings.<sup>4</sup></li> <li>In a post-hoc analysis, claims for highly anticholinergic medications were associated with an 85% increased risk of dementia and no adjustments were made for multiple other medication classes which could precipitate cognitive decline.</li> </ul>
<b>Hypomagnesemia</b>  5. FDA Drug Safety Communication: <a href="http://www.fda.gov/Drugs/DrugSafety/ucm245011.htm">http://www.fda.gov/Drugs/DrugSafety/ucm245011.htm</a>	<ul style="list-style-type: none"> <li>FDA Drug Safety Communication, March 2011 based on cases reported to the organization as well as published reports.<sup>5</sup></li> <li>Time to onset ranged from 3 - 12 months, with most cases being reported after at least 1 year of use. There is an additive risk with concurrent use of thiazide or loop diuretics.</li> <li>After discontinuation, median time to resolution is 7 days. Upon rechallenge, median time to recurrence is 2 weeks.</li> <li>About 25% of cases are refractory to supplementation and require cessation of therapy. Case reports suggest effect is maintained despite substitution to another PPI.</li> </ul>
<b>Fractures</b>  6. FDA Drug Safety Communication: <a href="http://www.fda.gov/Drugs/DrugSafety/PostmarketDrugSafetyInformationforPatientsandProviders/ucm213206.htm">http://www.fda.gov/Drugs/DrugSafety/PostmarketDrugSafetyInformationforPatientsandProviders/ucm213206.htm</a> 7. Khalili et al. BMJ Jan 2012	<ul style="list-style-type: none"> <li>FDA Drug Safety Communication May 2010 based on multiple observational trials.<sup>6</sup></li> <li>Risk appears to be dose and duration dependent, begins to emerge after at least 1 year of use, and is believed to be greater among patients with other risk factors including age &gt;50 years and smoking.</li> <li>One of the largest trials reported an absolute risk difference of 0.051% (NNH 1960 patients treated for 8 years).<sup>7</sup></li> </ul>
<b>C. Diff</b>  8. FDA Drug Safety Communication: <a href="http://www.fda.gov/Drugs/DrugSafety/ucm290510.htm">http://www.fda.gov/Drugs/DrugSafety/ucm290510.htm</a> 9. Howell et al. Arch Int Med May 2010	<ul style="list-style-type: none"> <li>FDA Drug Safety Communication Feb 2012 based on multiple observational trials and meta-analyses.<sup>8</sup></li> <li>In trials, the magnitude of risk has varied (OR 1.4 - 2.75) and there is suggestion of higher risk with twice-daily therapy as well as additive risk among patients receiving antibiotics.<sup>9</sup></li> </ul>
<b>Pneumonia</b>  10. Eom et al. CMAJ Feb 2011 11. Filion et al. Gut April 2014	<ul style="list-style-type: none"> <li>Observational studies have yielded mixed results and interpretation is limited by the high potential for confounding.</li> <li>One large meta-analysis found patients receiving PPIs or H2 blockers had a slight increase risk of pneumonia relative to those with no antisecretory therapy (OR 1.27 and 1.22, respectively).<sup>10</sup></li> <li>A second meta-analysis looking exclusively at PPIs for prophylaxis among new-start NSAID users found no association with PPIs or H2 blockers.<sup>11</sup></li> </ul>
<b>B12 &amp; Iron Malabsorption</b>  12. Lam et al. JAMA Dec 2013	<ul style="list-style-type: none"> <li>PPIs have been shown to cause a slight reduction in B12 absorption and have been associated with an increased risk of deficiency. It is reasonable to consider PPIs as a potential cause of B12 deficiency in patient receiving long-term therapy<sup>12</sup></li> <li>The clinical relevance of reduced iron absorption is questionable and may be most applicable to patient receiving oral iron supplements.</li> </ul>
